

Microneedling is a minimally invasive procedure done under topical anesthetic. Micropunctures are produced on the affected area at predetermined depth using tiny needles. This induces collagen formation within the skin and with repeated treatments will improve acne scarring, stretch marks and skin laxity. Mild treatment can also be used for rejuvenation.

The effects of microneedling is enhanced by the introduction of Nano cells of placenta (regeneration), mesenchyme (skin firming) or skin (hydration) during the procedure.
